<sup>2</sup> Higher Institute of Engineering, 15 May

**Abstract.** The paper presents the effect of reinforcement parameters on the structural behavior of steel fiber reinforced concrete (SFRC) corbels using the general-purpose ANSYS computer program. The parameters studied herein include the effect of fiber index ( $I_f$ ), ratio of the main longitudinal steel reinforcement ( $\rho_s$ ), yield strength of the longitudinal steel reinforcement ( $f_y$ ), ratio of the horizontal stirrups ( $\rho_h$ ), yield strength of the horizontal stirrups ( $f_{yh}$ ) and ratio of the vertical stirrups ( $\rho_v$ ). It is predicted that increase of  $I_f$  improves shear capacity and strain ductility. Steel fiber delays the premature failure for corbels. Increasing  $\rho_s$  improves the shear capacity but reduces the strain ductility. A slight increase in shear capacity is observed by increasing  $f_y$ . An enhancement on shear capacity and strain ductility is noticed by increasing  $\rho_h$ . On the other hand, a slight increase in shear capacity and reduction in ductility for corbels is observed by increasing  $f_{yh}$ . It is found that minimum  $\rho_v$  is required only to improve the shear capacity and strain ductility

**KEYWORDS:** Reinforced concrete corbels; Steel fibers; Load-deflection curves; Load-steel strain curves; Crack patterns; Finite element; ANSYS.

## 1. INTRODUCTION

Corbels are short cantilever members that project from a column or a wall to support another beam or heavy concentrated load. The importance of these members is clear in precast buildings where corbels support beams and girders. Corbels are characterized by a shear span-to-depth ratio ( $a/d$ ) lower than unity. Over the years, the contribution of steel fibers parameters has been studied on the structural behavior of concrete corbels [3-6]. It was found that steel fibers could replace partially or fully the stirrups. In addition, using steel fiber improves the ductility and toughness of the reinforced concrete corbels.

The aim of this paper is to present the results of reinforcement parametric studies on the performance of (SFRC) corbels using ANSYS computer program [1]. Numerical model was developed [2] and used successfully to predict the structural response of the tested SFRC corbels [3-6]. The main parameters include the effect of fiber index ( $I_f$ ), ratio of the main longitudinal steel reinforcement ( $\rho_s$ ), yield strength of the longitudinal steel reinforcement ( $f_y$ ), ratio of the horizontal stirrups ( $\rho_h$ ), yield strength of the horizontal stirrups ( $f_{yh}$ ) and ratio of the vertical stirrups ( $\rho_v$ ).

## 2. Modeling of SFRC Corbels

### 2.1 Model Description of the Tested Corbels

For the parametric study, finite element modeling is made for SFRC corbel that experimentally tested in [3]. Figure (1) shows the geometrical and reinforcement details for the SFRC corbel. In order to investigate the effect of different parameters; series of SFRC corbels, which labeled with (S1, S2...S18) are analyzed.

Figure (1) Corbels Geometrical and Steel Reinforcement Details[3]

### 2.2 Finite Element Geometric and Material Idealization

The finite element modeling and nonlinear analysis is performed by using ANSYS software [1]. The structural element types used to discrete the different

materials are given in Table 1. The 3-D finite element model made by ANSYS software is shown in Figure (2). The formulation of related elements is given in [2]. For concrete in compression, Hognestad-Popvics stress-strain curve [7] is used. For concrete in tension, a linear-tension softening curve is used [8]. Bilinear stress-strain curve is adopted for steel reinforcement in compression and tension. The concrete models were modified to take the effect of steel fiber inclusion[2]. Nonlinear incremental-iterative solution technique is used to follow material nonlinearities in compression and tension.

**Table 1: Structural Element Types Used to Discrete the Numerical Models**

Material	Structural Element
Fibrous Concrete	SOLID 65
Non-fibrous Concrete	SOLID 65
Steel bars	LINK 8
Bearing and Loading Plates	SOLID 45

**3. Parametric Studies**

Table 2 presents the parameters used in this study. Fiber index ( $I_f$ ) is defined as a function of steel fiber volume ( $V_f$ ), fiber aspect ratio ( $l_f/\phi_f$ ) and shape factor of steel fiber ( $\lambda$ ) as follows [8]:

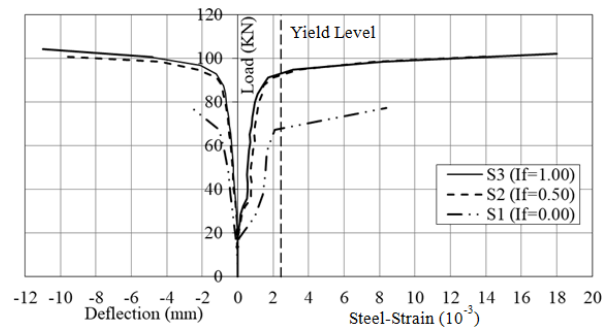

$$I_f = V_f \frac{l_f}{\phi_f} \lambda(1)$$

**Table 2: The Input Parameters for the Analyzed Specimens [2]**

Corbel	$I_f$	$\rho_{s=\frac{A_s}{b.d}}$ %	$f_y$ (MPa)	$\rho_{h=\frac{A_h}{b.S}}$ %	$f_{yh}$ (MPa)	$\rho_{s=\frac{A_s}{b.S}}$ %

S14	0.60	0.613	488	1.77	360	---
S15	0.60	0.613	488	1.77	445	---
S16	0.60	0.613	488	---	---	---
S17	0.60	0.613	488	---	---	1.77
S18	0.60	0.613	488	---	---	4.90

**3.1. Effect of Fibber Index**

Three SFRC corbels were analyzed with different  $I_f$  values. The values used are (0.0, 0.50 and 1.0) respectively for (S1, S2 and S3). The load-deflection curves and the load-steel strain curves for the analyzed specimens are plotted in Figure(3). The crack patterns are shown in Figure (4) for S1, S2 and S3.

**Figure (3) Predicted Response Curves for Corbels S1, S2 and S3**

**Figure (4) Crack Patterns for Corbels S1, S2 and S3**

The comparison between the given results indicates that increasing  $I_f$  leads to an enhancement in shear capacity ( $V_u$ ) by 31% and 35% for specimens S2 and S3.

S3 when compared to S1. Also, it increases the longitudinal steel strain ( $\epsilon_s$ ) for corbels S2 and S3 respectively by 67% and 114%. In addition, strain ductility has been increased. The calculated strain ductility (= ultimate strain/yield strain) is 3.4, 5.8 and 7.4 for S1, S2 and S3 respectively. Compared to specimen S1, the increase of  $I_f$  delays the possibility of premature shear failure and also leads to more spreading in cracks through corbel length and depth. Accordingly, steel fiber can replace partially or fully the horizontal stirrups. Significant enhancement in the toughness (I) which calculated from the area under the load-deflection curve is observed due to the increase in  $I_f$ . Toughness is enhanced by 522% for specimen S2 and by 605% for specimen S3 compared to specimen S1.

**3.2. Ratio of Longitudinal Steel**

Three SFRC corbels were analyzed with different  $\rho_s$  values (0.613%, 0.883% and 1.325%) respectively for corbels (S4, S5 and S6). Figure (5) presents the predicted response curves for the analyzed specimens (S4, S5 and S6).

**Figure (5) Predicted Response Curves for Corbels S4, S5 and S6**

It is clear that increasing  $\rho_s$  improves shear capacity  $V_u$  of the specimens by 18.82% and 39.10% for S5 and S6 with respect to S4. Slight enhancement in the toughness (I) has been observed by 7.10% and 11.0% for specimens S5 and S6 respectively when compared to S4. On the other hand, increasing  $\rho_s$  decreases the steel strain ( $\epsilon_s$ ) and strain ductility. The predicted decrease of ( $\epsilon_s$ ) is 37.5% and 73.0% for S5 and S6 respectively. The predicted values of strain ductility are 6.96, 3.0, and 1.95 for S4, S5 and S6 respectively.

**3.3. Yield Strength of the Longitudinal Steel**

Three SFRC corbels were analyzed with different ( $f_y$ ). The values used are (360, 420 and 488 MPa) respectively for corbels (S7, S8 and S9). Figure (6) represents the predicted response curves for specimens (S7, S8 and S9). The increase of  $f_y$  leads to a slight increase in shear capacity ( $V_u$ ) by 4.50% and 13.22% respectively for specimens S8 and S9 with respect to S7. On the other hand, a significant decrease in strain ductility is observed due to increase  $f_y$ .

**Figure (6) Predicted Response Curves for Corbels S7, S8 and S9**

**3.4. Effect of the Horizontal Stirrups Ratio**

Three corbels with different horizontal stirrups ratio  $\rho_h$  have been investigated. The corbels are denoted by S10, S11 and S12 and reinforced with  $\rho_h$  of values 0.0%, 1.77% and 4.90% respectively. Figures (7) and (8) present the predicted response curves and the crack patterns respectively for the analyzed specimens.

**Figure (7) Predicted Response Curves for Corbels S10, S11 and S12**

**Figure (8) Crack Patterns for Corbels S10, S11 and S12**

An enhancement in shear capacity ( $V_u$ ) by 20.20% and 32.46% has been observed for S11 and S12 respectively when compared with S10. With respect to S10, significant enhancement in the toughness (I) and strain ductility is noticed. The predicted increase in toughness (I) is 194% for specimen S11 and 512% for specimen S12. The predicted values of strain ductility are 3.34, 6.43, and 7.69 for S10, S11 and S12 respectively. Compared with specimen S10 the increase of  $\rho_h$  delays the possibility of premature shear failure and leads to more spreading in cracks through corbel length and depth.

**3.5. Yield Strength of the Horizontal Stirrups**

Three corbels were analyzed with different  $f_{yh}$ . The used values are (240, 360 and 445 MPa) respectively for corbels (S13, S14 and S15). Figure (9) presents the predicted response curves for the analyzed

specimens. Increasing  $f_{yh}$  leads to slight increases in shear capacity ( $V_u$ ). In addition, it decreases the ductility by 10% and 36% respectively for specimens S14 and S16 with respect to S13.

**Figure (9) Predicted Response Curves for Corbels S13, S14 and S15**

### 3.6. Ratio of Vertical Stirrups of Corbels

Three SFRC corbels S16, S17 and S18 having  $\rho_v$  0.0%, 1.77% and 4.90% respectively are chosen to investigate effect of  $\rho_v$ . The stirrups ratio  $\rho_v = 1.77\%$  is the minimum requirement for vertical stirrups content. The predicted response curves for the specimens are shown in Figure (10).

**Figure (10) Predicted Response Curves for Corbels S16, S17 and S18**

As shown in the figure, providing minimum vertical stirrups ( $\rho_{v, min}$ ) in corbels leads to increase shear capacity ( $V_u$ ) and strain ductility respectively by 13% and 20% for specimen S17 with respect to specimen S16. On the other hand, using  $\rho_v$  more than  $\rho_{v, min}$  has a negligible effect on shear capacity and the strain ductility of SFRC corbels.

### Conclusions

From the results obtained from the numerical results for reinforcement parameters, the following conclusions can be drawn:

1. The inclusion of steel fiber in corbels improves the shear capacity and the strain ductility. Compared with non-fibrous corbel, the use of corbel with  $I_f = 0.50$  and 1.0 increases respectively the shear capacity ( $V_u$ ) by 31% and 35% and the strain ductility by 70% and 117%.
2. Increasing the longitudinal steel ratio ( $\rho_s$ ) improves shear capacity ( $V_u$ ) but reduces the strain ductility of SFRC corbels. Compared with corbel with  $\rho_s = 0.613\%$ , the use of corbels with  $\rho_s = 0.883\%$  and 1.325% enhances

respectively ( $V_u$ ) by 18.82% and 39.10% and decreases the strain ductility by 56% and 71%. On the other hand, using corbels with  $f_y = 420$  MPa and 488 MPa leads to a slight increase in ( $V_u$ ) by 4.50% and 13.22% when compared to corbel with  $f_y = 360$  MPa.

3. Compared with corbel without  $\rho_h$ , significant improvement in toughness (I) is observed respectively by 194% and 512% for corbels with  $\rho_h = 1.77\%$  and 4.90%. Also,  $V_u$  is improved by 20.20% and 32.46% with respect to corbel without  $\rho_h$ . On the other hand, a slight increase in ( $V_u$ ) is observed respectively by 1% and 3% when using corbel with  $f_{yh} = 360$  MPa and 445 MPa with respect to corbel with  $f_{yh} = 240$  MPa.
4. It is important to provide  $\rho_{v, min}$  for corbels to improve the shear capacity and strain ductility but using  $\rho_v$  more than  $\rho_{v, min}$  has a negligible effect on the structural response of SFRC corbels.

## I. Manuscript Preparation General Guide Lines

1. Authors should prepare the manuscript, clearly legible. Headings and subheadings should be used throughout the text to divide the subject matter into its important, logical parts.
2. The manuscript must be compatible with Microsoft Word (MS). A MS word template for the manuscript is available in the site of the journal.
3. Articles should be submitted in English with a short abstract written in Arabic (if possible) of up to 200 words.
4. It is preferable to prepare the manuscript in the following order:
  - a. Title should be short but informative.
  - b. Author(s), full name, affiliation and address.
  - c. Abstract of not more than 400 words in English and Arabic (if possible).
  - d. Keywords should be included.
  - e. Text illustrations, figures and/or photographs should appear consecutively throughout the text.
  - f. Conclusions.
  - g. Acknowledgments, (if any).
  - h. Nomenclature (if any).
5. All sections and subsections should be numbered.
6. SI units should be used. Other units may be given in parenthesis.
7. All mathematical and special symbols must be typewritten using MS equation editor and defined in the text when they first appear.
8. If a list of symbols is needed, it should be arranged alphabetically under the Nomenclature section.
9. References citations within the body of the manuscript are given as Arabic numerals. These numerals are the same type size and font as the text material. The numerals are enclosed in square brackets [ ].
10. References must be written in the order they are cited in the text.

11. The Editorial Board reserves all rights to make stylistic and/or grammatical changes.
12. The Editorial Board's decisions regarding suitability for publication are final. The Board reserves the right not to justify these decisions.
13. The corresponding author will receive one official hard copy of the article in addition to a PDF copy of the article.
14. The copyright of the article is transferred to Engineering Research Journal (ERJ) after the article is accepted for publication. The copyright transfer covers the exclusive right to reproduce and distribute the article. These include reprints, translations, photographic reproductions, electronic form (offline or online) or any other reproductions of similar nature.

## II. Manuscript Submission General Guide Lines

1. Original contributions submitted for publications will be refereed and fall into one of the following categories:
  - a. Full length research article.
  - b. Review articles.
  - c. Technical notes.
2. Papers presented at technical conferences are acceptable for submission to the journal.
3. Authors can submit their manuscripts to Editorial in Chief via email: [erj@feng.bu.edu.eg](mailto:erj@feng.bu.edu.eg).
4. Clearly indicate who is responsible for correspondence at all stages of refereeing and publication, including post-publication. On the manuscript, the corresponding author should be indicated. Ensure that the telephone and email (with country and region code) are provided.
