

## CHAPTER SIX

### INTERPOLATING BETWEEN DATA POINTS

In this chapter we will study linear interpolation and Newton's forward and backward formulae which are used for readings at equal intervals.

. Interpolation is a procedure for determining a value of  $y$  corresponding to some specified value of  $x$ , when  $x$  falls between two known values, say  $x_i$  and  $x_{i+1}$ .

. The goal in interpolation is to determine the value of  $y$  as accurately as possible by passing an equation through the data points themselves rather than through the aggregate of the data points (as discussed in the last Chapter).

. The equation of interpolation need not be passed through all of the data points but just the data points within the immediate area of interest.

. The number of data points included in the equation generally depends on the nature of the interpolation curve (straight line or polynomial) and the level of accuracy required in the interpolated value.

## LINEAR INTERPOLATION

. The graph shown contains two data points:

$$p_1 = (x_1, y_1), \quad p_2 = (x_2, y_2)$$

and we wish to determine the value of  $y$  corresponding to some specified value of  $x$ , where

$$x_1 < x < x_2.$$

. By connecting the two data points  $p_1$  and  $p_2$  with a straight line, the desired value of  $y$  at the specified value of  $x$  can be determined as:

$$y = y_1 + \frac{y_2 - y_1}{x_2 - x_1}(x - x_1)$$

**Example:**

Given the two data points (2.0, 5.5) and (2.1, 7.2). Determine the value of  $y$  corresponding to  $x = 2.03$  using linear interpolation.

*Solution:* We have,

$$x_1 = 2.0 \quad y_1 = 5.5$$

$$x_2 = 2.1 \quad y_2 = 7.2$$

$$x = 2.03$$

Substituting in Eq. (6.1), we get

$$y(2.03) = 5.5 + [(7.2 - 5.5) / (2.1 - 2.0)] * (2.03 - 2.0) = 6.01$$

Thus, the new interpolated data point is (2.03, 6.01).

*Solution of the Example using Excel:*

	A	B	C	D	E	F	G
1	x	y					
2	2	5.5					
3	2.1	7.2					
4							
5	2.03	6.01					
6							

## POLYNOMIAL INTERPOLATION

### a) FORWARD DIFFERENCES

. Suppose we wish to fit an interpolating polynomial through a number of equally spaced data points rather than a linear interpolation, as shown in the Figure below.

. Forward difference is defined as:

$$\Delta y_i = y_{i+1} - y_i$$

It is called the forward difference because it is obtained by subtracting the current point ( $y_i$ ) from the forward point ( $y_{i+1}$ ).

We can extend this concept to higher differences by writing

$$\Delta^2 y_i = \Delta y_{i+1} - \Delta y_i$$

$$\Delta^3 y_i = \Delta^2 y_{i+1} - \Delta^2 y_i$$

.....

$$\Delta^k y_i = \Delta^{k-1} y_{i+1} - \Delta^{k-1} y_i$$

Thus we can construct the following table of forward differences for a data set consisting of six data points:

$x_i$	$y_i$	$\Delta y_i$	$\Delta^2 y_i$	$\Delta^3 y_i$	$\Delta^4 y_i$	$\Delta^5 y_i$
$x_1$	$y_1$	$\Delta y_1$	$\Delta^2 y_1$	$\Delta^3 y_1$	$\Delta^4 y_1$	$\Delta^5 y_1$
$x_2$	$y_2$	$\Delta y_2$	$\Delta^2 y_2$	$\Delta^3 y_2$	$\Delta^4 y_2$	
$x_3$	$y_3$	$\Delta y_3$	$\Delta^2 y_3$	$\Delta^3 y_3$		
$x_4$	$y_4$	$\Delta y_4$	$\Delta^2 y_4$			
$x_5$	$y_5$	$\Delta y_5$				
$x_6$	$y_6$					

. The interpolated value  $y$  at a specified  $x$  can be given by using the *Gregory-Newton forward interpolating* formula given as:

$$y = y_1 + \frac{u}{h} \Delta y_1 + \frac{u(u-h)}{2!h^2} \Delta^2 y_1 + \frac{u(u-h)(u-2h)}{3!h^3} \Delta^3 y_1 + \dots$$

where:

$h$  = equal spacing between the given  $x$  values (e.g.,  $h = x_2 - x_1$ )

$u = x - x_1$

**Example:**

Use the forward interpolation Equation to interpolate the value of  $y$  corresponding to  $x = 1.7$  for the given set of data:

$x_i$	$y_i$
1	1
2	2
3	10
4	44
5	141
6	366

**Solution:** We start the solution by constructing the forward difference table.

$x_i$	$y_i$	$\Delta y_i$	$\Delta^2 y_i$	$\Delta^3 y_i$	$\Delta^4 y_i$	$\Delta^5 y_i$
1	1	1	7	19	18	10
2	2	8	26	37	28	
3	10	34	63	65		
4	44	97	128			
5	141	225				
6	366					

$$h = 1$$

$$x = 1.7 \quad x_1 = 1 \quad u = (x - x_1) = 0.7$$

$$y_1 = 1 \quad \Delta y_1 = 1 \quad \Delta^2 y_1 = 7 \quad \Delta^3 y_1 = 19 \quad \Delta^4 y_1 = 18 \quad \Delta^5 y_1 = 10$$

**Substituting these values into the Equation, we obtain:**

$$y(1.7) = 1.5312475$$

### Solution of the Example using Excel:

The screenshot shows a Microsoft Excel window titled "Microsoft Excel - chap6-2". The formula bar contains the following formula for cell B9:

$$=B2+J2*C2/J3+J2*(J2-J3)*D2/(2*J3^2)+J2*(J2-J3)*(J2-2*J3)*E2/(6*J3^3)+J2*(J2-J3)*(J2-2*J3)*(J2-3*J3)*F2/(24*J3^4)+J2*(J2-J3)*(J2-2*J3)*(J2-3*J3)*(J2-4*J3)*G2/(120*J3^5)$$

The spreadsheet data is as follows:

	A	B								
1	x	y								
2	1	1	1	7	19	18	10		u=	0.7
3	2	2	8	26	37	28			h=	1
4	3	10	34	63	65					
5	4	44	97	128						
6	5	141	225							
7	6	366								
8										
9	1.7	1.5312								
10										
11										

### b) BACKWARD DIFFERENCES

Forward difference interpolation works well when the interpolation point is near the beginning of the data set. On the other hand, backward differences provide a more accurate result when the interpolation point is near the end of the data set.

. Backward difference is defined as:

$$\nabla y_i = y_i - y_{i-1}$$

It is called the backward difference because it is obtained by subtracting the backward point ( $y_{i-1}$ ) from the current point ( $y_i$ ).

. We can extend this concept to higher differences by writing

$$\nabla^2 y_i = \nabla y_i - \nabla y_{i-1}$$

$$\nabla^3 y_i = \nabla^2 y_i - \nabla^2 y_{i-1}$$

.....

$$\nabla^k y_i = \nabla^{k-1} y_i - \nabla^{k-1} y_{i-1}$$

Thus we can construct the following table of backward differences for a data set consisting of six data points:

$x_i$	$y_i$	$\nabla y_i$	$\nabla^2 y_i$	$\nabla^3 y_i$	$\nabla^4 y_i$	$\nabla^5 y_i$
$x_1$	$y_1$					
$x_2$	$y_2$	$\nabla y_2$				
$x_3$	$y_3$	$\nabla y_3$	$\nabla^2 y_3$			
$x_4$	$y_4$	$\nabla y_4$	$\nabla^2 y_4$	$\nabla^3 y_4$		
$x_5$	$y_5$	$\nabla y_5$	$\nabla^2 y_5$	$\nabla^3 y_5$	$\nabla^4 y_5$	
$x_6$	$y_6$	$\nabla y_6$	$\nabla^2 y_6$	$\nabla^3 y_6$	$\nabla^4 y_6$	$\nabla^5 y_6$

The interpolated value  $y$  at a specified  $x$  can be given by using the *Gregory-Newton backward interpolating formula* given as:

$$y = y_1 + \frac{u}{h} \nabla y_1 + \frac{u(u+h)}{2!h^2} \nabla^2 y_1 + \frac{u(u+h)(u+2h)}{3!h^3} \nabla^3 y_1 + \dots$$

**Example:**

Use Equation (6.3) to interpolate the value of  $y$  corresponding to  $x = 5.7$  for the given set of data:

$x_i$	$y_i$
1	1
2	2
3	10
4	44
5	141
6	366

**Solution:** First we construct the backward difference table.

$x_i$	$y_i$	$\nabla y_i$	$\nabla^2 y_i$	$\nabla^3 y_i$	$\nabla^4 y_i$	$\nabla^5 y_i$
1	1					
2	2	1				
3	10	8	7			
4	44	34	26	19		
5	141	97	63	37	18	
6	366	225	128	65	28	10

$$h = 1$$

$$x = 5.7 \quad x_1 = 6 \quad u = (x - x_1) = -0.3$$

$$y_1 = 366 \quad \nabla y_1 = 225 \quad \nabla^2 y_1 = 128 \quad \nabla^3 y_1 = 65 \quad \nabla^4 y_1 = 28 \quad \nabla^5 y_1 = 10$$

**Substituting these values into the backward interpolation Equation, we obtain:**

$$y(5.7) = 279.7707$$

***Solution of Example (3) using Excel:***

The screenshot shows a Microsoft Excel window titled "Microsoft Excel - chap6-3". The formula bar contains the following complex mathematical expression:

$$=B7+J6*C7/J7+J6*(J6+J7)*D7/(2*J7^2)+J6*(J6+J7)*(J6+2*J7)*E7/(6*J7^3)+J6*(J6+J7)*(J6+2*J7)*(J6+3*J7)*F7/(24*J7^4)+J6*(J6+J7)*(J6+2*J7)*(J6+3*J7)*(J6+4*J7)*G7/(120*J7^5)$$

The spreadsheet data is as follows:

	A	B							
1	x	y							
2	1	1							
3	2	2	1						
4	3	10	8	7					
5	4	44	34	26	19				
6	5	141	97	63	37	18		u=	-0.3
7	6	366	225	128	65	28	10	h=	1
8									
9	5.7	279.7707
