

### Examples for Parabolic Antenna

- 1- A parabolic dish with diameter of 3ft operates at 10GHZ , determine the approximate gain , beam width , and the distance for farfield region operation , The illumination efficiency is 55% .

#### Solution

$$D=3\text{ft}=36 \text{ inch} \quad , \quad \text{ft}=12 \text{ inch} \quad , \quad \text{inch} = 2.5 \text{ cm} .$$

$$D=36*2.5 = 90 \text{ cm}$$

$$f=10\text{GHZ}$$

$$\lambda = \frac{c}{f} = \frac{3*10^8}{10*10^9} = 0.03\text{m} = 3 \text{ cm} .$$

$$\text{Gain} = e_A \left( \frac{\pi D}{\lambda} \right)^2 = 0.55 \left( \frac{\pi * 90}{3} \right)^2 = 5047 \quad \text{where } e_A \text{ is illumination efficiency}$$

$$\text{-Gain (db)} = 10 \log(5047) = \mathbf{37} .$$

$$\text{-Beamwidth} = k \left( \frac{\lambda}{D} \right) = \mathbf{70} \left( \frac{3}{90} \right) = 2.29^\circ$$

For a "typical" parabolic antenna  $k$  is approximately **70**.

$$\text{-the distance for farfield} \quad R > \frac{2D^2}{\lambda} = 183\text{ft or } 2196 \text{ inch} .$$

- 1- 2m radius parabolic dish is sufficient for receiving signal at frequency of 12 GHZ , what is the required distance to receive same level of signal at frequency 6GHZ.

#### Solution

$$D_1=2r_1= 2*2=4\text{m} \quad , \quad f_1=12\text{GHZ} \quad , \quad f_2=6\text{GHZ}/$$

$$\lambda_1 = c/f_1 = 0.025\text{m} .$$

$$\lambda_2 = c/f_2 = 0.05\text{m} .$$

same level of signal means

$$\text{Gain}_1 = \text{Gain}_2$$

$$e_A \left( \frac{\pi D_1}{\lambda_1} \right)^2 = e_A \left( \frac{\pi D_2}{\lambda_2} \right)^2$$

$$\left(\frac{D_1}{\lambda_1}\right) = \left(\frac{D_2}{\lambda_2}\right)$$

$$D_2=8m \quad ,, \quad r_2=4m .$$

3-Assuming Aperture efficiency is 70% , what is the gain of parabolic dish antenna as function of it's radius.

Solution

Aperture efficiency is 70% ( K=70% )

$$D=2r$$

$$\text{Gain} = e_A \left(\frac{\pi D}{\lambda}\right)^2$$

$$G=0.7 \left(\frac{\pi * 2r}{\lambda}\right)^2$$

$$G=0.7 \frac{4\pi^2 * r^2}{\lambda^2}$$

$$G=27.6 \left(\frac{r^2}{\lambda^2}\right)$$

4- 1m diameter parabolic dish is used as receiving antenna for satellite TV reception at 6GHZ ,, determine at 3GHZ the HPBW if the same level of signal is received .

Solution

- $D_1=1m$  ,,
- $F_1= 6GHZ$  ,  $F_2=3GHZ$ .

$$\lambda_1 = c/F_1 = 0.05 \text{ m .}$$

$$\lambda_2 = c/F_2 = 0.1 \text{ m .}$$

the same level of signal means

$$G_1 = G_2$$

$$e_A \left(\frac{\pi D_1}{\lambda_1}\right)^2 = e_A \left(\frac{\pi D_2}{\lambda_2}\right)^2$$

$$\left(\frac{D_1}{\lambda_1}\right) = \left(\frac{D_2}{\lambda_2}\right)$$

$$D_2=2m \quad , \quad r_2=1m$$

$$\text{-HPBW} = K \left( \frac{\lambda}{D} \right) = 70 \left( \frac{\lambda}{D} \right)$$

-For a "typical" parabolic antenna  $k$  is approximately **70**.

- If we choose  $\lambda_1$  &  $D_1$

$$\text{HPBW} = 70 \left( \frac{\lambda_1}{D_1} \right)$$

$$\text{HPBW} = 3.5^\circ$$

5- Calculate the directivity of an antenna with circular aperture of diameter 3m of frequency 5GHZ ..

Solution

$$D=3\text{m} , r=1.5\text{m} .$$

$$F=5\text{GHZ} .$$

$$\lambda = C/f = 0.06\text{m}$$

$$\text{circular aperture} , A_{\text{emax}} = \pi r^2 .$$

$$A_{\text{emax}} = A_e \text{ as } \eta = 100\% .$$

$$A_e = \pi r^2 = \pi (1.5)^2 .$$

$$\text{Directivity} = \frac{4\pi A_e}{\lambda^2}$$

$$\text{Directivity} = 24674$$

### Example on spherical reflector

-for a given maximum aperture size there exists a maximum value of total allowable phase error, and it is given by

$$\left(\frac{a}{R}\right)_{\max}^4 = 14.7 \frac{(\Delta/\lambda)_{\text{total}}}{(R/\lambda)}$$

- where  $(\Delta/\lambda)$  is the total phase error in wavelengths

### Example 15.4

A spherical reflector has a 10-ft diameter. If at 11.2 GHz the maximum allowable phase error is  $\lambda/16$ , find the maximum permissible aperture.

*Solution:* At  $f = 11.2$  GHz

$$\lambda = 0.08788 \text{ ft}$$

$$\left(\frac{a}{R}\right)_{\max}^4 = 14.7 \left(\frac{1/16}{56.8957}\right) = 0.01615$$

$$a^4 \approx 10.09$$

$$a = 1.78 \text{ ft}$$
